Chronic Diarrhea in Adults

INTRODUCTION
Chronic diarrhea is defined as loose stools that last for at least four weeks. This usually means three or more loose stools per day. There are many possible causes of chronic diarrhea. Treatment is aimed at correcting the cause of diarrhea (whenever possible), firming up loose stools, and dealing with any complications of diarrhea.

Chronic diarrhea can have a substantial impact on your quality of life and overall health. At its mildest, diarrhea is an inconvenience; at its worst, it may be disabling and even life threatening. Fortunately, effective treatments are available.

CHRONIC DIARRHEA CAUSES
A wide range of problems can cause chronic diarrhea; some of the most common causes include irritable bowel syndrome, inflammatory bowel disease (Crohn's disease and ulcerative colitis), malabsorption syndromes, and chronic infections. There are also many other less common causes of chronic diarrhea.

Irritable bowel syndrome — Irritable bowel syndrome (IBS) is one of the most common causes of chronic diarrhea. IBS can cause crampy abdominal pain and changes in bowel habits (diarrhea, constipation, or both). IBS can develop after having an infection.

Inflammatory bowel disease — There are several types of inflammatory bowel disease, two of the most common of which are Crohn's disease and ulcerative colitis. These conditions may develop when the body's immune system attacks parts of the digestive tract.

Infections — Intestinal infections, sometimes called "food poisoning," are an uncommon cause of chronic diarrhea in people who live in developed countries, such as the United States. Infections that cause chronic diarrhea can be seen in people who travel or live in tropical or developing countries, especially older adults and those affected by HIV. Intestinal infections can also develop after eating contaminated food or drinking contaminated water or unpasteurized ("raw") milk.

Endocrine disorders — An overactive thyroid (hyperthyroidism) can cause chronic diarrhea and weight loss. Diabetes can cause chronic diarrhea if the nerves that supply the digestive tract are injured.

Food allergy or sensitivity — Food allergies and hypersensitivity can cause chronic diarrhea. People with celiac disease often have diarrhea and weight loss.

Medicines — Medicines (prescription and nonprescription), herbs, and dietary supplements can cause diarrhea as a side effect. To determine if a medicine could be the cause of your diarrhea, review your list of medicines with your doctor, nurse, or pharmacist. This information may also be available on the medicine bottle or paperwork that comes with most prescriptions.
**CHRONIC DIARRHEA EVALUATION**
You should seek medical attention if you have loose or watery stools that last more than four weeks. You may need to be seen sooner than this if you have complications of diarrhea (eg, bloody diarrhea, fever, dehydration, or weight loss).

During your visit, it is important to mention when your diarrhea began, any recent changes in medicines or medical problems, and if you have had accidents (leaking or smearing of stool in the underwear).

**Tests** — Blood, stool, and urine tests can help to find the underlying cause of diarrhea. If these tests do not find the cause, other approaches may be needed, including X-rays or procedures, such as colonoscopy or sigmoidoscopy.

**CHRONIC DIARRHEA TREATMENT**
Treatment of chronic diarrhea aims to eliminate the underlying cause (if the cause is known), firm up the bowel movements, and treat any diarrhea-related complications.

**Treating the cause** — The underlying cause of chronic diarrhea should be found and treated whenever possible. For example, infections may be treated with antibiotics. In people with Crohn's disease or ulcerative colitis, long-term treatment and follow-up is needed. In some cases, treatment may be as simple as eliminating a food or medicine. For people with lactose intolerance, this may include foods or drinks that contain lactose.

Other ingredients that are known to cause diarrhea include sugar-free products made with sorbitol and foods made with fat replacements (eg, Olestra®). Certain medicines can also cause diarrhea (such as laxatives and antacids).

**Treating diarrhea** — In some people, the goal is simply to have less diarrhea. This approach is often used before testing, when the results of tests are normal or not helpful, or if diarrhea is caused by a chronic medical problem.

Diarrhea treatments include:
1. Bismuth (sold as Kaopectate®, Pepto-Bismol®)
2. Treatments that bulk the stools, such as a high-fiber diet or fiber supplement
3. Antidiarrhea medicines, such as loperamide (sold as Imodium®, available without a prescription) or prescription medicines, such as diphenoxylate (Lomotil®)
4. Octreotide, a prescription medicine that might be given to people with severe diarrhea

**Treatment trial** — Your doctor or nurse might recommend trying a treatment before further testing. This approach can help to narrow down the list of possible causes of your diarrhea. Treatments that might be offered include:
1. A trial of antibiotics, for an infection
2. Stopping a medicine
3. Changing your diet, for a possible food allergy or problem absorbing nutrients (such as lactose intolerance)
Treating complications — Chronic or severe diarrhea can lead to potentially serious complications, including dehydration and malnutrition. While you are being evaluated, you should be sure to drink plenty of fluids. You are drinking enough fluids if your urine is a light yellow color.

If you are not able to drink enough fluids and you become dehydrated, you may be given fluids into a vein (IV) to replace the fluids and electrolytes (salts) lost in diarrhea. This will not cure your diarrhea, but it can prevent more serious complications.
